What is this assignment about and why is it important? (audience, purpose and context)

As a future computer scientist, you will need to show and present the data your are collecting, analyzing or modelling to your colleagues and peers. Here the most important steps to do that properly.

What should you do? How should it look like?

Select a data set of your preference. By now you should know already what data you want to use for your final report. Having selected the data, the assignment has the following steps:

1. Start by pointing down information about two things: (i) the data source (where did you get the data?) and (ii) the variables (what is the data about?). If it is a big data set, think which variables you will need, but keep notice about the "extra" information the data set is providing. You might need it later...
2. Now think how to *show* your data. Depending on the data, it may be better to make e.g. a scatter plot or a table. Give some time to think which is the best way to show the data you will use for your analysis.
3. Explain in one or two paragraphs what do you intend to do with the data. How do you want to analyze it? Make some prediction? What exactly? Remember that by having a clear idea about what you want to do with the data, will help you afterwards selecting the proper tools to do that.

Layout and format: The maximum size is two pages. There is no minimum size. The description must have a title.
